Welcome to FIS Securities Finance Trading Manager || The version **10.5.0** of Securities Finance Trading Manager is released on 31st March 2

Benefits

Benefits

REAL-TIME POSITIONS MANAGEMENT AND TRADE CAPTURE

Provides a fast, reliable, and scalable architecture that brings together trading activity across your firm and aggregates this information in real-time. It helps you consolidate your global inventory across multiple products, regions, countries, trading desks and legal entities.

SETTLEMENT AND INSTRUCTION PROCESSING

Provides efficient trade settlement, incorporating a high degree of straight-through processing helping you to control the operational costs of your securities finance and repo business.

AUDIT AND CONTROL

Allows for your firm to record and track all static or trade lifecycle changes. Provides complete flexibility to allow or restrict user access and easily monitor changes in the system.

▼ BEFORE YOU BEGIN

These documents describes the (Undefined variable: Variables.ECNSystemName) interface, one of a number of ECN interfaces that can be used with Apex Securities Finance (Apex SF or Apex) FIS Securities Finance Trading Manager.

These document contains certain conventions and special symbols that are used throughout.

Keyboard

Warnings

Warnings are used to indicate that it is possible that an action or lack of action will result in the loss of vital information in your application. For example:

We recommend that you take a backup of your database before uninstalling Apex.

Notes

Notes are used to provide additional information. For example:

Depending upon which profile the user accounts are configured to use, the relevant .profile script must be updated with all of the relevant Apex environment variables.

Tips

Tips provide helpful hints or generally useful information. They may also provide a quicker way to do something. For example:

Alternatively, right-click a row in the browser, and select the relevant option on the shortcut menu.

▼ IN THIS HELP

This help content is organized as follows:

- **FAQs and Troubleshooting:** Frequently asked questions and troubleshooting guide that can help the user resolve the issues independently.
- **Getting Started:** Contains the prerequisites and getting started information of Securities Finance Trading Manager.
- **Installation and Configuration:** Understand prerequisites and detailed instructions on installing and configuring the product.
- **Release Notes:** Get an overview of new features and enhancements introduced, and bugs fixed in this release.
- **User Guide:** Understand how to use the features of an application, service, or product.

Select Content

Depending on the product, the help content you are viewing can have multiple versions. You can select the topic associated with a particular version of the product/release using the version selector.

Installation and Configuration

These Installation and Configuration Guides help you install, configure and setup various components of FIS Securities Trading Manager.

Getting Started

This section has all the guides required to start with FIS Securities Finance Trading Manager.

User Guides

These user guides help the user to understand the functionalities and help the users to use the product better.

Release Notes

This section helps you with all the Release Notes. The Release Notes are segregated based on the product versions and their releases.

FAQs and Troubleshooting

This section helps you with the Frequently Asked Questions and the Troubleshooting guide

Release Policy

This section helps you with all the Release Policy documents.

This section helps you with all the Release Notes. The Release Notes are segregated based on the product versions and their releases.

FIS Securities Finance Trading Manager 9

FIS Securities Finance Trading Manager 10

FIS Securities Finance Trading Manager 11

This page contains the Release Notes for different releases. The release notes document includes details about the fixes and improvements made during the release, as well as any hotfix updates. The version numbering follows this pattern: X.Y.Z, where X is the Major version, Y is the Minor version, and Z is the latest hotfix version.

The most recent document includes the content from the previous hotfix versions.

9.0.2 Release Notes

9.1.1 Release Notes

9.2.3 Release Notes

9.3.0 Release Notes

9.4.1 Release Notes

9.5.0 Release Notes

Download Guide

Welcome to the guide for the Release Notes of version 9.0.x of FIS Securities Finance Trading Manager (SFTM). This resource outlines essential hotfixes and highlights from the major release, version 9.0.0. It is designed to keep users informed, with the most relevant updates readily accessible. The tab title will display the latest hotfix version, using "x" to indicate the most current update. We encourage you to explore the content.

Summary

This section provides the summary of corrections and enhancements in release 9.0.0.

9.0.2 Hotfix

This section describes the Hotfixes in release 9.0.2 in the following functional domains:

9.0.1 Hotfix

This section describes the Hotfixes in release 9.0.1 in the following functional domains:

9.0.0 Corrections

This section describes the corrections in release 9.0.0 in the following functional domains:

- Double-click the Apex icon on your desktop, or select Apex from the Programs list.

Logging In

To log into Apex:

1. Select the appropriate **Password Type** from the list. The type you select will dictate the behaviour of the **Username** and **Password** fields:

- **Database**, select this option to log in using a Database password.
- **Kerberos SSO**, select this option to use Kerberos with single sign on (SSO). You will not be required to enter a user name or password.
- **LDAP**, select this option to use LDAP authentication. You will be required to enter your password each time you open the Apex client.

When LDAP users have made multiple attempts to login their LDAP password validation locks out after three attempts. To re-login, an admin user has to un-suspend the account. A site configuration key **BypassFailedLoginsForExtAuth** controls the bypass of the failed login attempts. For more information about Password Types, see the *Apex Help*.

- **LDAP (Auto Logon)**, select this option to use LDAP authentication with auto logon. You will not be required to enter a user name or password; your Windows credentials will be used.
- **External**, select this option to use external authentication. You will not be required to enter a user name or password in Apex; your Windows credentials will be used. Depending on the authentication service used, you may or may not be required to enter a user name or password during authentication.
- **External (Auto Logon)**, select this option to use external authentication with auto logon. You will not be required to enter a user name or password in Apex; your Windows credentials will be used. Depending on the authentication service used, you may or may not be required to enter a user name or password during authentication.

If a user has made multiple failed attempts to login, only the user with Database password validation gets locked out after three attempts. All other login types do not display failed login attempt. For more information about Password Types, see the *Apex Help*.

2. If a user name is required, ensure that your correct user name is shown in the **Username** field.
3. If a password is required, enter it in the **Password** field. Note that it is case sensitive.
4. If this is the first time you have logged on, Apex prompts you to change your password from the default given to you by the System Administrator.
5. Select the relevant **Environment**.
6. Select any or all of the following options:
 - **Restore Workspace** – restores the workspace that you saved in a previous session.
 - **Validate Database Schema** – when selected, the system checks that the database is suitable for use with the version of Apex that is running.

You can select this option when you first start to use Apex, and then deselect it to speed up login during normal use.

- **Use Calc Manager** – when selected, reduces the load on the database by using the CalcManager to retrieve data. The CalcManager caches commonly requested information to improve overall performance.

Apex verifies your credentials before proceeding with your login.

Audit

There are a number of auditing features within Apex that monitor changes to all types of data. All changes within Apex are identified by the ID of the user making the change and the date and time of the modification.

When a change is made, a record is made of the information before the change and after the change. This information is stored in XML format in the Oracle database. The Audit Trail Browser in the Apex graphical user interface can be used to view these changes. The user can also make use of Oracle's support for XML to generate customised queries and specific audit reports.

In addition to trade events and changes to static data, all user logins and changes to permissions and limits, such as price tolerance, are logged and can be viewed on the Audit Trail Browser. The history of all changes to static data can be viewed on the appropriate browser, including the User Admin Browser, which shows the history of changes to tasks that users can perform, such as entering or marking trades or changing security details. Changes to an individual trade or an associated trade, including fee, rate and price changes, can be seen on the trade itself.

Load Balancing

To achieve load balancing within an Apex installation, additional server machines are required. The business services can be load balanced by installing additional instances of the services on separate machines. The client's configuration files would then be changed in one of two ways. If the client applications are run from a shared file server with a shared configuration file, the hostnames of the additional machines should be added to the file. The client application then chooses one of the server machines randomly. This method of load balancing also achieves some level of fault tolerance for the business services, because if one service goes down, the clients can use one of the services on the other machines.

If the client applications are installed locally on the PC and they do not share a configuration file, each application can either use a specific server machine or the application can choose a server randomly from a list of possible server machines (recommended), which offers the advantage of some degree of fault tolerance.

Load balancing can also be achieved by taking advantage of the features of the chosen Java Application Server. For example, some Java Application Servers provide clustering support that enables multiple servers to appear as a single server and to dynamically load balance JMS, JDBC and HTTP traffic.

Fault Tolerance

Apex can be configured to provide different levels of fault tolerance, depending on the installation. Hardware fault tolerance is typically achieved by having secondary application servers that can take over from the primary application server in the event of failure. Other measures, such as "striping" the network so alternate client workstations are on different network segments, or having each client workstation connected to an additional backup network segment, can improve network fault tolerance.

In a global implementation of Apex with multiple application servers, each application server can act as a backup to the other servers because each server holds an identical data set. If the local application server fails, the client workstations can connect to the nearest remote application server and continue to read and write data to that database. When the local application server recovers, it automatically re-synchronises by reading the transactions from the remote databases.

If the network becomes unavailable, the Apex client application continues to run, but in an off-line mode; the client does not receive real-time messages, but the screens can use any existing data in the cache. When the network comes back online, the client applications must be restarted in order to reconnect to the messaging bus and receive real-time messages.

Fault tolerance can also be achieved by taking advantage of the features of the chosen Java Application Server. For example, some Java Application Servers support JDBC managed connection pools that can take advantage of multiple servers. Failure of a single server reduces the capacity of the connection pool, but dependent services can tolerate the server failure.
